I have a tree data structure that should display some information on a per-item basis - similar to how groups work in Gmail. Is there a performant way to do this in Flex? I was trying to use groups but the datagrid doesn't seem to work well with them (especially when working with millions of records that are in hundreds of sub-groups). Thanks. A: Every collection that is tied to a scrolling list has two features that make it hard to scroll or search effectively. It must know the size of its children. This is usually done via a custom collection class that simply has a field holding the size of its children. It must be able to efficiently remove items, even when multiple items at the same index are removed. See Removing Items. To handle both 1 and 2, Flex has a feature called "item-based memory". It basically keeps the items in a list in memory, indexed by their position in the list. Whenever you remove an item, it is replaced by the previous item's offset. Whenever a new item needs to be added, it's added on top of the previous item's offset. If you don't use item-based memory, then it will need to know which items are children and which are not, which means it must iterate over the entire collection each time you need to do something. Removing items (or updates) may be extremely expensive in this model as it must iterate over every element in the list, and in a collection that has a lot of nodes, this can be a lot of work. In your case, item based memory will be an excellent solution. You simply create a custom data structure which has some extra fields that represent the group membership, and whenever you insert or update a new object into your parent
