[One-stage and 2-stage approaches for treatment of carious, partially-erupted teeth]. For the case of carious, partially-erupted teeth, one-stage and two-stage approaches are performed in accordance with the degree of dental caries and condition of the pulp. One-stage approach is selected when the dental caries is severe, and it is not possible to preserve the pulp tissue, and/or when the pulp condition is poor because of rapid pulp infection due to carious dental injury. Two-stage approach is performed after one-stage approach. This treatment consists of removing caries in a single visit. This will be followed by a second visit 3 weeks later when the pulp condition is confirmed and a decision is made whether or not to perform pulpectomy. In this second visit, it is confirmed that the pulp condition is well preserved and that the inflammatory reactions to the caries removal have subsided. Pulpectomy is performed in order to prevent pathological conditions of the pulp. The future of the AFL is as bright as it has ever been.
