No. 3,512,233. Both of these devices have a substantially semicircular armature which, in the presence of a magnetic field, is rotated by a rotating magnetic field. The two magnetic switches differ in the fact that, in the first instance, a stator magnet is employed which rotates along with the armature and, in the second instance, a magnetized armature is employed which rotates with the arm

Cartonography, also known as X-ray film imaging or X-ray graphic imaging, is a technique in which the static image on film for each picture is the remanent magnetization of the emulsion in the photographic medium, and not the magnetic field used to actually capture the image of the X-ray. Instead of X-rays impinging on the patient or object to be radiographed, an X-ray film in contact with the patient or object is used to record the desired picture on the emulsion. Cartography is used to name an emerging technique that is similar to X-ray, however, a digital image is obtained. Unlike film photography, the X-ray image may be manipulated by human intervention. For example, any subsequent rotation, cropping, zoom and scrolling are often possible, although it is usually necessary to choose the location from which to operate. Also, digital scans can be adjusted for brightness and contrast, and a variety of enhancements are available. The clarity of the image can be enhanced, and the image rotation can be corrected as well. Typically, the output data from a computed tomography (CT) or a magnetic resonance imaging (MRI) scanner comprises slices, voxels or cubes of data. These data are converted to film images by means of an image processor. The images can be stored in their original format, i.e. in cubic format, or in a flattened format for viewing on monitors. To produce an image of an object by CT (computed tomography), for example, the object is typically positioned in a defined position, for example a position within an imaging gantry. The gantry has an imaging volume which includes a x-ray source in its boundary. The x-rays are transmitted through the object in the volume and to the imaging volume. There, an x-ray detector array is positioned to receive x-rays transmitted through the object. The xrays are attenuated and attenuation patterns traverse the imaging volume of the gantry in space and/or in time. The detector array comprises an array of detectors, each detector comprising a scintillating material and associated optical circuitry for converting incident photons into, for example, electricity. The attenuation patterns can be converted into a two-dimensional
