Hindi.Thursday, November 09, 2013 Checklist for Submitting to the Journal of Popular Culture I have
just submitted the manuscript of my latest book, Gender and Genre in Popular Culture, to the journal
that eventually published Magic, Wonder, and the Dark Art of Power: The Collected Papers of James
Elroy. Like Magic, Wonder, and the Dark Art of Power, this book focuses on the role of genre and
gender in popular culture. I also include a chapter on the history of libraries and librarians and a
chapter on popular love and romance. I use a number of examples of genre representation in
popular culture to show how genre analysis enables us to interrogate processes of exclusion and
inclusion in film and popular culture. In my submission, I included chapter-length and shorter
articles. I sent a first round of 400 pages of 12 to 18. I asked my colleagues to suggest chapter titles
for the book. I have included their suggestions and mine below. I included the first two chapters of
my book ("Sex, Power, and Popular Culture," and "Gender and Genre in Popular Culture") as well as
several articles that I sent along with the manuscript. For the article "Gender and Genre in Popular
Culture: Representations and Forms of Gender Work

Hemoglobin (Hb) is a tetramer of two alpha and two beta chains. Hb is the main functional protein in erythrocytes. In erythrocytes, the tetramer molecules are arranged in an elongated cross-section showing a general diameter of 10-12 nm, such that each of the eight individual hemoglobin molecules is located at the center of a heme pocket. Hemoglobin has two allosteric binding sites, both of which can bind ligands such as oxygen and carbon dioxide. In the case of oxygen, the binding involves the cooperativity of four equidistant but independent oxygen binding sites. One of the two allosteric sites is the "proximal" site, located at the tertiary and quaternary structure level, near the interface between subunits. Binding of ligands to the proximal site is sensed by distal sites that affect physiological response to the binding of ligand. A distal site is usually referred to as R or T-state (regional or global, respectively) indicating a different functional environment of that site when compared to the R or T-state, respectively. Thus, the unliganded R-state binds ligands in a different functional manner than the T-state. The conditions under which these states occur can be determined in a study using an unliganded R-state to fully dissociate the ligand from the proximal site and subsequently ligating the R-state with a ligand. Usually, the ligand/site interaction is increased for the T-state and decreased for the R-state. A different allosteric system controls the oxygenation state of hemoglobin. In this system, the oxygenation state or oxygen affinity of hemoglobin is determined by cooperativity of the two ligand binding sites. Until recently, two major models of cooperativity were proposed. The first model is referred to as "symmetrical", for example, the model developed by Hessel and Benkovic (Hessel, P., et al., *Biochemistry*, 35, 3920-
